In mathematics, the Radon transform is the integral transform which takes a function f defined on the plane to a function Rf defined on the space of lines in the plane, whose value at a particular line is equal to the line integral of the function over that line. The transform was introduced in 1917 by Johann Radon, who also provided a formula for the inverse transform. Radon further included formulas for the transform in three dimensions, in which the integral is taken over planes. It was later

Radon transform - Wikipedia

The Radon transform is an important topic in integral geometry which deals with the problem of expressing a function on a manifold in terms of its integrals over certain submanifolds. Solutions to such problems have a wide range of applications, namely to partial differential equations, group representations, X-ray technology, nuclear magnetic resonance scanning, and tomography.

The Radon transform is a mapping from the Cartesian rectangular coordinates (x,y) to a distance and an angle (ρ,θ) , also known as polar coordinates. An example of the transform of an image for a specific angle is given in Figure 2.4 on page 6 and Figure 2.6 on page 7.

behind direct sampling type methods for the inversion of the Radon transform, including our detailed choices of probing and index functions. Section 3 provides mathematical justifications for the novel DSM and investigates how the choice of some critical parameters in the sampling algorithm affects the reconstruction.

The Radon Transform on \mathbb{R}^n $x + k \cdot \sim$ denoting the translate of the hyperplane $k \cdot \sim$ by x . The triangle inequality shows that $d(O, x + k \cdot \sim) \sim d(O, \sim) - |x|$, $x \in \mathbb{R}^n$, $k \in K$. Hence we conclude from assumptions (i) and (21) that (22) $U_z(\sim) = 0$ if $d(O, \sim) > A + |x|$.
